

Introduction

Hello everyone! My name is Jae Hyuk Sung, an author of this coding guidelines. I am glad to be able to write this guideline report.

I will introduce the task and the file you need to implement for each question. Since each question has lots of difficult parts, especially those that require mathematical knowledge, I will provide guidelines for solving them. Since this report is written in \LaTeX , it is written **only in English** for readability.

Also, you don't have to fill out the inline questions.

If you have any questions or comments, please feel free to let me know. Here is my contact information.

Q1. k-Nearest Neighbor classifier

Implement files

- *k_nearest_neighbor.py*
- *knn.ipynb*

k_nearest_neighbor.py

You need to implement a total of 4 functions: 3 functions depending on the number of iterations and 1 function predicting the actual label.

It is a bit easier for you to implement a function that uses two loops and one loop.

But, you have to construct mathematical formulas when coding with loops to implement the no-loop function. No loop function should take less than 0.1 second.

Hint: KNN implies that you need to express a matrix representation of the L2 distances.

Let $x = [x_1 \ x_2 \ \cdots \ x_t]^T$ is training set, and $y = [y_1 \ y_2 \ \cdots \ y_n]^T$ is object set, and distance matrix A has $n \times t$ size. (It also means $A[i, j]$ implies the distance with y_j and x_j .)

In other words, we can rewrite matrix A as follows:

$$A = \begin{bmatrix} \sqrt{y_0^2 - 2y_0x_0 + x_0^2} & \cdots & \sqrt{y_0^2 - 2y_0x_t + x_t^2} \\ \sqrt{y_1^2 - 2y_1x_0 + x_0^2} & \cdots & \sqrt{y_1^2 - 2y_1x_t + x_t^2} \\ \vdots & \ddots & \vdots \\ \sqrt{y_n^2 - 2y_nx_0 + x_0^2} & \cdots & \sqrt{y_n^2 - 2y_nx_t + x_t^2} \end{bmatrix}$$

For convenience, we define the element-wise function $f(W)$ which returns the square root of elements. Then, there exists a matrix B which satisfies $A = f(B)$.

Also, we can express B with another element-wise function and broadcasting, and Hadamard product.

Finally, you need to implement “predict_labels”, which returns the **index** of largest score. Note that I emphasize the index! You don't need to check the sorted array.

KNN.ipynb

Fortunately, functions in KNN are not difficult! You need to split data for cross-validation and perform k-fold cross-validation. *Hint:* Search for array_split function in NumPy package, and perform K-fold CV with three loops.

Q2. Support Vector Machine(SVM)
